# 1 Datasheet

The Intel® 50 Gbps Ethernet (50GbE) IP core implements the 25G & 50G Ethernet Specification, Draft 1.4 from the 25 Gigabit Ethernet Consortium and the IEEE 802.3by 25Gb Ethernet draft. The IP core includes an option to support unidirectional transport as defined in Clause 66 of the IEEE 802.3-2012 Ethernet Standard. The MAC client side interface for the 50 Gbps Ethernet IP core is a 128-bit Avalon® Streaming (Avalon-ST) interface. It maps to two 25.78125 Gbps transceivers.

The IP core provides standard media access control (MAC) and physical coding sublayer (PCS), and PMA functions shown in the following block diagram. The PHY comprises the PCS and PMA.

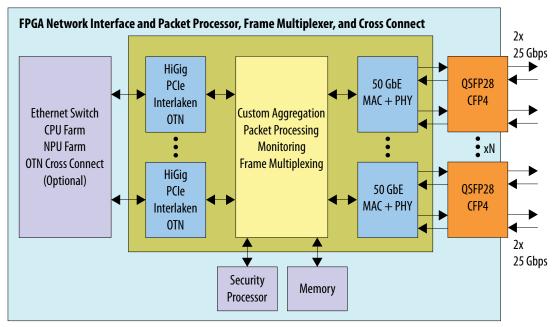

Figure 1. 50GbE MAC and PHY IP Clock Diagram

The following block diagram shows an example of a network application with 50GbE MAC and PHY.

Figure 2. Example Network Application

### 1.1 50GbE IP Core Supported Features

The 50GbE IP core is designed to the 25G & 50G Ethernet Specification, Draft 1.6 from the 25 Gigabit Ethernet Consortium and designed to the IEEE 802.3by 25Gb Ethernet specification, as well as the IEEE 802.3ba-2012 High Speed Ethernet Standard available on the IEEE website (www.ieee.org). The MAC provides RX cut-through frame processing to optimize latency. The IP core supports the following features:

- PHY features:
  - Soft PCS logic that interfaces seamlessly to Arria<sup>®</sup> 10 FPGA 25.78125 gigabits per second (Gbps) serial transceivers.
- Frame structure control features:
  - Support for jumbo packets, defined as packets greater than 1500 bytes.
  - Receive (RX) CRC removal and pass-through control.
  - Transmit (TX) CRC generation.
  - RX and TX preamble pass-through option for applications that require proprietary user management information transfer.
  - TX automatic frame padding to meet the 64-byte minimum Ethernet frame length.
- Frame monitoring and statistics:
  - RX CRC checking and error reporting.
  - Optional RX strict SFD checking per IEEE specification.
  - RX malformed packet checking per IEEE specification.
  - Optional fault signaling detects and reports local fault and generates remote fault, with IEEE 802.3ba-2012 Ethernet Standard Clause 66 support.
  - Unidirectional transport as defined in Clause 66 of the IEEE 802.3-2012 Ethernet Standard.
- Debug and testability features:
  - Programmable serial PMA local loopback (TX to RX) at the serial transceiver for self-diagnostic testing.
  - Optional access to Altera Debug Master Endpoint (ADME) for serial link debugging or monitoring PHY signal integrity.
- User system interfaces:
  - Avalon Memory-Mapped (Avalon-MM) management interface to access the IP core control and status registers.
  - Avalon Streaming (Avalon-ST) data path interface connects to client logic.
  - Ready latency of 0 clock cycles for Avalon-ST TX interface.
  - Hardware and software reset control.

For a detailed specification of the Ethernet protocol refer to the *IEEE 802.3 Ethernet Standard*.

### 1.2 50GbE IP Core Device Family and Speed Grade Support

### 1.2.1 Device Family Support

### Table 1. Intel IP Core Device Support Levels

Device Support Level	Definition
Preliminary	The IP core is verified with preliminary timing models for this device family. The IP core meets all functional requirements, but might still be undergoing timing analysis for the device family. It can be used in production designs with caution.
Final	The IP core is verified with final timing models for this device family. The IP core meets all functional and timing requirements for the device family and can be used in production designs.

### Table 2. 50GbE IP Core Device Family Support

Shows the level of support offered by the 50GbE IP core for each Intel device family.

<b>Device Family</b>	Support
Arria 10 GT	Default support level provided in the Quartus® Prime software. Refer to the <i>Quartus Prime</i> Standard Edition Software and Device Support Release Notes and the Quartus Prime Pro Edition Software and Device Support Release Notes.
Other device families	Not supported

#### **Related Links**

Reports the default device support levels in the current version of the Quartus Prime Pro Edition software.

### 1.2.2 50GbE IP Core Device Speed Grade Support

### **Table 3.** Slowest Supported Device Speed Grades

IP Core	Device Family	Supported Speed Grades
50GbE	Arria 10 GT	E2

### 1.3 IP Core Verification

To ensure functional correctness of the 50GbE IP core, Intel performs extensive validation through both simulation and hardware testing. Before releasing a version of the 50GbE IP core, Intel runs comprehensive regression tests in the current version of the Quartus Prime software.

Intel verifies that the current version of the Quartus Prime software compiles the previous version of each IP core. Any exceptions to this verification are reported in the *Intel FPGA IP Release Notes*. Intel does not verify compilation with IP core versions older than the previous release.

#### **Related Links**

Intel FPGA IP Release Notes

Changes to the IP core in major releases are noted in the 50GbE Intel FPGA IP Release Notes starting from the Quartus Prime software v17.0

 Quartus Prime Design Suite Update Release Notes Includes changes in minor releases (updates).

### 1.3.1 Simulation Environment

Intel performs the following tests on the 50GbE IP core in the simulation environment using internal and third-party standard bus functional models (BFM):

- Constrained random tests that cover randomized frame size and contents
- Assertion based tests to confirm proper behavior of the IP core with respect to the specification
- Extensive coverage of our runtime configuration space and proper behavior in all possible modes of operation

### 1.3.2 Compilation Checking

Intel performs compilation testing on an extensive set of 50GbE IP core variations and designs to ensure the Quartus Prime software places and routes the IP core ports correctly.

### 1.3.3 Hardware Testing

Intel performs hardware testing of the key functions of the 50GbE IP core using internal loopback and also with other 50G switches. The hardware tests also ensure reliable solution coverage for hardware related areas such as performance, link synchronization, and reset recovery.

### 1.4 Performance and Resource Utilization

The following table shows the typical device resource utilization for selected configurations using the current version of the Quartus Prime software. With the exception of M20K memory blocks, the numbers of ALMs and logic registers are rounded up to the nearest 100. The timing margin for this IP core is a minimum of 15%.

#### Table 4. Performance and Resource Utilization for 50GbE IP Core

The following results are for a variant that excludes all optional features.

Product ALMs De		Dedicated Logic Registers	M20K Memory Blocks
50GbE	9300	18600	3

# 1.5 Release Information

#### Table 5. **50GbE IP Core Current Release Information**

Item	Description	
Version	17.0	
Release Date	2017.05.08	
Ordering Codes	IP-50GEUMACPHY (IPR-50GEUMACPHY for renewal)	

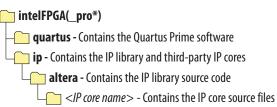

# 2 Getting Started

### 2.1 Installing and Licensing IP Cores

The Intel Quartus Prime software installation includes the Intel FPGA IP library. This library provides useful IP core functions for your production use without the need for an additional license. Some IP cores in the library require that you purchase a separate license for production use. The OpenCore® feature allows evaluation of any Intel FPGA IP core in simulation and compilation in the Quartus Prime software. Upon satisfaction with functionality and performance, visit the Self Service Licensing Center to obtain a license number for any Intel FPGA product.

The Quartus Prime software installs IP cores in the following locations by default:

### Figure 3. IP Core Installation Path

### **Table 6. IP Core Installation Locations**

Location	Software	Platform
<pre><drive>:\intelFPGA_pro\quartus\ip\altera</drive></pre>	Quartus Prime Pro Edition	Windows*
<pre><drive>:\intelFPGA\quartus\ip\altera</drive></pre>	Quartus Prime Standard Edition	Windows
<pre><home directory="">:/intelFPGA_pro/quartus/ip/altera</home></pre>	Quartus Prime Pro Edition	Linux*
<pre><home directory="">:/intelFPGA/quartus/ip/altera</home></pre>	Quartus Prime Standard Edition	Linux

### 2.1.1 OpenCore Plus IP Evaluation

The free OpenCore Plus feature allows you to evaluate licensed MegaCore IP cores in simulation and hardware before purchase. Purchase a license for MegaCore IP cores if you decide to take your design to production. OpenCore Plus supports the following evaluations:

- Simulate the behavior of a licensed IP core in your system.
- Verify the functionality, size, and speed of the IP core quickly and easily.
- Generate time-limited device programming files for designs that include IP cores.
- Program a device with your IP core and verify your design in hardware.

Intel Corporation. All rights reserved. Intel, the Intel logo, Altera, Arria, Cyclone, Enpirion, MAX, Nios, Quartus and Stratix words and logos are trademarks of Intel Corporation or its subsidiaries in the U.S. and/or other countries. Intel warrants performance of its FPGA and semiconductor products to current specifications in accordance with Intel's standard warranty, but reserves the right to make changes to any products and services at any time without notice. Intel assumes no responsibility or liability arising out of the application or use of any information, product, or service described herein except as expressly agreed to in writing by Intel. Intel customers are advised to obtain the latest version of device specifications before relying on any published information and before placing orders for products or services.

9001:2008 Registered

OpenCore Plus evaluation supports the following two operation modes:

- Untethered—run the design containing the licensed IP for a limited time.
- Tethered—run the design containing the licensed IP for a longer time or indefinitely. This operation requires a connection between your board and the host computer.

Note:

All IP cores that use OpenCore Plus time out simultaneously when any IP core in the design times out.

### 2.2 Specifying the 50GbE IP Core Parameters and Options

The 50GbE parameter editor allows you to quickly configure your custom IP variation. Use the following steps to specify IP core options and parameters in the Quartus Prime software.

- Depending on whether you are using the Quartus Prime Pro Edition software or the Quartus Prime Standard Edition software, perform one of the following actions:
  - In the Quartus Prime Pro Edition, click File ➤ New Project Wizard to create
    a new Quartus Prime project, or File ➤ Open Project to open an existing
    Quartus Prime project. The wizard prompts you to specify a device.
  - In the Quartus Prime Standard Edition software, in the IP Catalog (Tools ➤ IP Catalog), select the Arria 10 target device family.
- 2. In the IP Catalog (**Tools** ➤ **IP Catalog**), locate and double-click the name of the IP core to customize. The New IP Variation window appears.
- 3. In the **New IP Variation** dialog box, specify a top-level name for your custom IP variation. The parameter editor saves the IP variation settings in a file named <your\_ip>.qsys (in Quartus Prime Standard Edition) or <your\_ip>.ip (in Quartus Prime Pro Edition).
- 4. In the Quartus Prime Standard Edition software, you must select a specific Arria 10 device in the **Device** field, or keep the default device the Quartus Prime software proposes.
- 5. Click **OK**. The parameter editor appears.
- 6. On the **IP** tab, specify the parameters for your IP core variation. Refer to 50GbE IP Core Parameters on page 19 for information about specific IP core parameters.
- 7. Optionally, to generate a simulation testbench or compilation and hardware design example, follow the instructions in the *Arria 10 50G Ethernet Design Example User Guide*.
- 8. Click **Generate HDL**. The **Generation** dialog box appears.
- 9. Specify output file generation options, and then click **Generate**. The IP variation files generate according to your specifications.

Note: A functional VHDL IP core is not available. Specify Verilog HDL only, for your IP core variation.

- 10. Click Finish. The parameter editor adds the top-level .qsys or .ip file to the current project automatically. If you are prompted to manually add the .qsys or .ip file to the project, click Project ➤ Add/Remove Files in Project to add the file.
- 11. After generating and instantiating your IP variation, make appropriate pin assignments to connect ports.

### 2.3 Simulating the IP Core

You can simulate your 50GbE IP core variation with the functional simulation model and the testbench generated with the IP core. The functional simulation model is a cycle-accurate model that allows for fast functional simulation of your IP core instance using industry-standard Verilog HDL simulators. You can simulate the Intel-provided testbench or create your own testbench to exercise the IP core functional simulation model.

The functional simulation model and testbench files are generated in project subdirectories. These directories also include scripts to compile and run the design example.

Note:

Use the simulation models only for simulation and not for synthesis or any other purposes. Using these models for synthesis creates a nonfunctional design.

In the top-level wrapper file for your simulation project, you can set the the following RTL parameters to enable simulation optimization. These optimizations significantly decrease the time to reach link initialization.

- SIM\_SHORT\_RST: Shortens the reset times to speed up simulation.
- SIM\_SHORT\_AM: Shortens the interval between alignment markers to accelerate alignment marker lock.
- SIM\_SIMPLE\_RATE: Sets the PLL reference clock (clk\_ref) to 625 MHz instead of 644.53125 MHz to optimize PLL simulation model behavior

In general, parameters are set through the IP core parameter editor and you should not change them manually. The only exceptions are these simulation optimization parameters.

To set these parameters on the PHY blocks, add the following lines to the top-level wrapper file:

```
defparam <dut instance>.SIM_SHORT_RST = 1'b1;
defparam <dut instance>.SIM_SHORT_AM = 1'b1;
defparam <dut instance>.SIM_SIMPLE_RATE = 1'b1;
```

Note:

You can use the example testbench as a guide for setting the simulation parameters in your own simulation environment. These lines are already present in the Intel-provided testbench for the IP core.

### 2.4 Generated File Structure

The Quartus Prime software generates the following IP core output file structure.

For information about the file structure of the design example, refer to the *Arria 10 50GbE Design Example User Guide*.

Figure 4. IP Core Generated Files

#### Table 7. **IP Core Generated Files**

File Name	Description
<pre><your_ip>.qsys (Quartus Prime Standard Edition only)</your_ip></pre>	The Qsys system or top-level IP variation file. <pre><your_ip></your_ip></pre> is the name that you give your IP variation.
<pre><your_ip>.ip (Quartus Prime Pro Edition only)</your_ip></pre>	give your it variation.
<system>.sopcinfo</system>	Describes the connections and IP component parameterizations in your Qsys system. You can parse its contents to get requirements when you develop software drivers for IP components.  Downstream tools such as the Intel Nios® II tool chain use this file.  The .sopcinfo file and the system.h file generated for the Nios II tool chain include address map information for each slave relative to each master that accesses the slave. Different masters may have a different address map to access a particular slave component.
<pre><your_ip>.cmp</your_ip></pre>	The VHDL Component Declaration (.cmp) file is a text file that contains local generic and port definitions that you can use in VHDL design files.  This IP core does not support VHDL. However, the Quartus Prime software generates this file.
<pre><your_ip>.html</your_ip></pre>	A report that contains connection information, a memory map showing the address of each slave with respect to each master to which it is connected, and parameter assignments.
<pre><your_ip>_generation.rpt</your_ip></pre>	IP or Qsys generation log file. A summary of the messages during IP generation.
<pre><your_ip>.debuginfo</your_ip></pre>	Contains post-generation information. Used to pass System Console and Bus Analyzer Toolkit information about the Qsys interconnect. The Bus Analysis Toolkit uses this file to identify debug components in the Qsys interconnect. (Quartus Prime Standard Edition only)
<pre><your_ip>.qgsimc</your_ip></pre>	Lists simulation parameters to support incremental regeneration. (Quartus Prime Pro Edition only)
<pre><your_ip>.qgsynthc</your_ip></pre>	Lists synthesis parameters to support incremental regeneration. (Quartus Prime Pro Edition only)
<pre><your_ip>.qip</your_ip></pre>	Contains all the required information about the IP component to integrate and compile the IP component in the Quartus Prime software.
<pre><your_ip>.csv</your_ip></pre>	Contains information about the upgrade status of the IP component.
<pre><your_ip>.bsf</your_ip></pre>	A Block Symbol File (. <b>bsf</b> ) representation of the IP variation for use in Quartus Prime Block Diagram Files (. <b>bdf</b> ).
<pre><your_ip>.spd</your_ip></pre>	Required input file for ip-make-simscript to generate simulation scripts for supported simulators. The <b>.spd</b> file contains a list of files generated for simulation, along with information about memories that you can initialize.
<pre><your_ip>.ppf</your_ip></pre>	The Pin Planner File (.ppf) stores the port and node assignments for IP components created for use with the Pin Planner.
<pre><your_ip>_bb.v</your_ip></pre>	You can use the Verilog black-box ( <b>_bb.v</b> ) file as an empty module declaration for use as a black box.
<pre><your_ip>.sip</your_ip></pre>	Contains information required for NativeLink simulation of IP components. You must add the <b>.sip</b> file to your Quartus Prime project. (Quartus Prime Standard Edition only)
<pre><your_ip>_inst.v and _inst.vhd</your_ip></pre>	HDL example instantiation template. You can copy and paste the contents of this file into your HDL file to instantiate the IP variation.  This IP core does not support VHDL. However, the Quartus Prime software generates the _inst.vhd file.

File Name	Description		
<pre><your_ip>.regmap</your_ip></pre>	If IP contains register information, <b>.regmap</b> file generates. The <b>.regmap</b> file describes the register map information of master and slave interfaces. This file complements the <b>.sopcinfo</b> file by providing more detailed register information about the system. This enables register display views and user customizable statistics in the System Console.		
<pre><your_ip>.svd</your_ip></pre>	Allows hard processor system (HPS) System Debug tools to view the register maps of peripherals connected to HPS within a Qsys system.  During synthesis, the .svd files for slave interfaces visible to System Console masters are stored in the .sof file in the debug section. System Console reads this section, which Qsys can query for register map information. For system slaves, Qsys can access the registers by name.		
<pre><your_ip>.v and <your_ip>.vhd</your_ip></your_ip></pre>	HDL files that instantiate each submodule or child IP core for synthesis or simulation.  This IP core does not support VHDL. However, the Quartus Prime software generates this file.		
mentor/	Contains a ModelSim script msim_setup.tcl to set up and run a simulation.		
aldec/	Contains a Riviera-PRO script rivierapro_setup.tcl to setup and run a simulation.		
synopsys/vcs/ synopsys/vcsmx/	Contains a shell script vcs_setup.sh to set up and run a VCS® simulation.  Contains a shell script vcsmx_setup.sh and synopsys_ sim.setup file to set up and run a VCS MX® simulation.		
cadence/	Contains a shell script ncsim_setup.sh and other setup files to set up and run an NCSIM simulation.		
submodules/	Contains HDL files for the IP core submodule.		
<pre><child cores="" ip="">/</child></pre>	For each generated child IP core directory, Qsys generates synth/ andsim/ sub-directories.

Information about the 50GbE design example file structure.

### 2.5 Integrating Your IP Core in Your Design

### 2.5.1 Pin Assignments

When you integrate your 50GbE IP core instance in your design, you must make appropriate pin assignments. While compiling the IP core alone, you can create virtual pins to avoid making specific pin assignments for top-level signals. When you are ready to map the design to hardware, you can change to the correct pin assignments.

### **Related Links**

#### Quartus Prime Help

For information about the Quartus Prime software, including virtual pins.

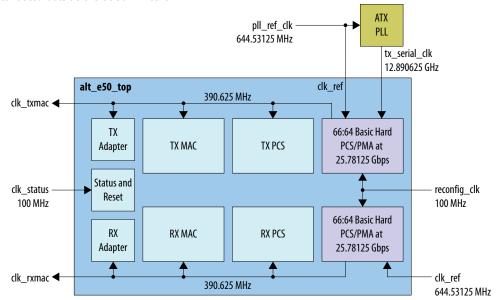

### 2.5.2 Adding the Transceiver PLL

The 50GbE IP core targets Arria 10 GT devices. Arria 10 GT devices require an external PLL to drive the TX transceiver serial clock, in order to compile and to function correctly in hardware.

### Figure 5. PLL Configuration Example

The TX transceiver PLL is instantiated with an ATX PLL IP core. The TX transceiver PLL must always be instantiated outside the 50GbE IP core.

You can use the IP Catalog to create a transceiver PLL.

- Select Arria 10 Transceiver ATX PLL.
- In the parameter editor, set the following parameter values:
  - PLL output frequency to 12890.625 MHz. The transceiver performs dual edge clocking, using both the rising and falling edges of the input clock from the PLL. Therefore, this PLL output frequency setting supports a 25.78125 Gbps data rate through the transceiver.
  - PLL reference clock frequency to 644.53125 MHz.

You must connect the ATX PLL to the 50GbE IP core as follows:

- Connect the clock output port of the ATX PLL to the tx\_serial\_clk input pin for each 50GbE IP core PHY link to the same output port of the ATX PLL. Connect the ATX PLL output port to both tx serial clk[1] and tx serial clk[0].
- Connect the pll\_locked output port of the ATX PLL to the tx\_pll\_locked input port of the 50GbE IP core.
- Drive the ATX PLL reference clock port and the 50GbE IP core clk\_ref input port
  with the same clock. The clock frequency must be the frequency you specify for
  the ATX PLL IP core PLL reference clock frequency parameter.

#### **Related Links**

- Transceivers on page 36

Information about the correspondence between PLLs and transceiver channels, and information about how to configure an external transceiver PLL for your own design. You specify the clock network to which the PLL output connects by setting the clock network in the PLL parameter editor.

### 2.5.3 Handling Potential Jitter in Arria 10 Devices

The RX path in the 50GbE IP core includes cascaded PLLs. Therefore, the IP core clocks might experience additional jitter in Arria 10 devices.

Refer to the KDB Answer *How do I compensate for the jitter of PLL cascading or non-dedicated clock path for Arria 10 PLL reference clock?* for a workaround you should apply to the IP core, in your design.

#### **Related Links**

https://www.altera.com/support/support-resources/knowledge-base/tools/2017/fb470823.html

KDB Answer: How do I compensate for the jitter of PLL cascading or non-dedicated clock path for Arria 10 PLL reference clock?

### 2.5.4 Placement Settings for the 50GbE IP Core

The Quartus Prime software provides the options to specify design partitions and  $LogicLock^{(g)}$  or LogicLock Plus regions for incremental compilation, to control placement on the device. To achieve timing closure for your design, you might need to provide floorplan quidelines using one or both of these features.

The appropriate floorplan is always design-specific, and depends on your full design.

#### **Related Links**

Describes incremental compilation, design partitions, and LogicLock Plus regions.

# 2.6 Compiling the Full Design and Programming the FPGA

You can use the **Start Compilation** command on the Processing menu in the Quartus Prime software to compile your design. After successfully compiling your design, program the targeted Intel FPGA with the Programmer and verify the design in hardware.

Note: The 50GbE IP core design example synthesis directories include Synopsys Constraint (.sdc) files that you can copy and modify for your own design.

For additional .sdc file requirements, please refer to the KDB Answer at https://www.altera.com/support/support-resources/knowledge-base/tools/2017/fb470823.html.

Information about generating the design example and the design example directory structure.

# **3 50GbE IP Core Parameters**

The 50GbE parameter editor provides the parameters you can set to configure the 50GbE IP core and simulation testbenches.

The 50GbE parameter editor includes an **Example Design** tab. For information about that tab, refer to the *50G Ethernet Design Example User Guide*.

Table 8. IP Core Parameters

Parameter	Range	<b>Default Setting</b>	Description		
General Options					
Device Family Arria 10 Arria 10 Se			Selects the device family.		
		MAC Optio	ns		
Enable link fault generation	Enabled, Disabled	Disabled	When enabled, the IP core implements link fault signaling as defined in the IEEE 802.3-2012 IEEE Standard for Ethernet. The MAC includes a Reconciliation Sublayer (RS) to manage local and remote faults. When enabled, the local RS TX logic can transmit remote fault sequences in case of a local fault and can transmit IDLE control words in case of a remote fault.		
Enable strict SFD checking	Enabled, Disabled	Disabled	When enabled, the IP core can implement strict SFD checking, depending on register settings.		
Enable preamble passthrough	Enabled, Disabled	Disabled	When enabled, the IP core is in RX and TX preamble pass-through mode. In RX preamble pass-through mode, the IP core passes the preamble and Start Frame Delimiter (SFD) to the client instead of stripping them out of the Ethernet packet. In TX preamble pass-through mode, the client specifies the preamble and provides the SFD to be sent in the Ethernet frame.		
	Configur	ation, Debug and	Extension Options		
Enable Altera Debug Master Endpoint (ADME)	Enabled, Disabled	Disabled	If enabled, the IP core turns on the following features in the Arria 10 PHY IP core that is included in the 50GbE IP core:  • Enable Altera Debug Master Endpoint (ADME)  • Enable capability registers  If turned off, the IP core is configured without these features.  For information about these Arria 10 features, refer to		
			the Arria 10 Transceiver PHY User Guide

# **4 Functional Description**

### 4.1 50GbE IP Core Functional Description

The Intel FPGA 50GbE IP core implements an Ethernet MAC in accordance with the 25G & 50G Ethernet Specification. The IP core implements an Ethernet PCS and PMA (PHY) that handles the frame encapsulation and flow of data between a client logic and Ethernet network.

Figure 6. 50GbE IP Core MAC and PHY Clock Diagram

In the TX direction, the MAC assembles packets and sends them to the PHY. It completes the following tasks:

- Accepts client frames
- Inserts the inter-packet gap (IPG), preamble, start of frame delimiter (SFD), and padding

The PHY encodes MAC frames for reliable transmission over the media to the remote end.

In the RX direction, the PMA passes frames to the PCS that sends them to the MAC. The MAC completes the following tasks:

- Performs CRC and malformed packet checks
- Strips out the CRC, preamble, and SFD
- Passes the remainder of the frame to the client

9001:2008 Registered UG-20021 | 2017.11.07

In preamble pass-through mode, the MAC passes on the preamble and SFD to the client instead of stripping them out. In RX CRC pass-through mode, the MAC passes on the CRC bytes to the client and asserts the end-of-packet signal in the same clock cycle as the final CRC byte.

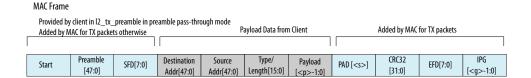

### 4.1.1 50GbE IP Core TX Datapath

The TX MAC module receives the client payload data with the destination and source addresses. It then adds, appends, or updates various header fields in accordance with the configuration specified. The MAC does not modify the destination address, the source address, or the payload received from the client. However, the TX MAC module adds a preamble, if the IP core is not configured to receive the preamble from user logic. It pads the payload of frames greater than eight bytes to satisfy the minimum Ethernet frame payload of 46 bytes. The MAC inserts the CRC bytes. The TX MAC module inserts IDLE bytes to maintain an average IPG of 12.

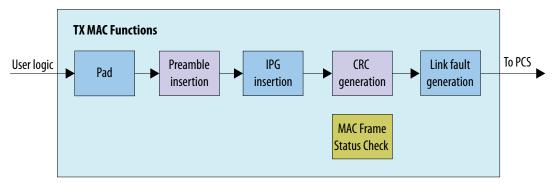

### Figure 7. Typical Client Frame at the Transmit Interface

Illustrates the changes that the TX MAC makes to the client frame. This figure uses the following notational conventions:

- $\langle p \rangle$  = payload size, which is arbitrarily large
- $\langle s \rangle$  = number of padding bytes (0-46)
- $\langle g \rangle$  = number of IPG bytes

### Figure 8. TX MAC Functions

### 4.1.1.1 Frame Padding

When the length of the client frame is less than 64 bytes, the TX MAC module inserts pad bytes (0x00) after the payload to create a frame length equal to the minimum size of 64 bytes (including CRC).

The IP core filters out all client frames with lengths less than 9 bytes. The IP core drops these frames silently.

#### 4.1.1.2 Preamble Insertion

In the TX datapath the MAC prepends an eight-byte preamble to the client frame. If you turn on **Enable link fault generation**, this MAC module also incorporates the functions of the reconciliation sublayer (RS).

The source of the 7-byte preamble (including a Start byte) and 1-byte SFD depends on whether you turn on **Enable preamble passthrough** in the parameter editor.

If the preamble pass-through feature is enabled, the client provides the eight-byte preamble (comprising seven bytes of preamble, and final 1-byte SFD) on a dedicated preamble bus, 12\_tx\_preamble[63:0]. In this case, the client is responsible for providing the correct Start byte (0xFB) and an appropriate SFD byte. If the preamble pass-through feature is disabled, the MAC inserts the standard Ethernet preamble in the transmitted Ethernet frame.

When  $12\_tx\_startofpacket$  is asserted,  $12\_tx\_preamble[63:0]$  contains the preamble data and  $12\_tx\_data[127:0]$  contains the first 16 bytes of frame data, starting from destination address.

Note that a single parameter in the 50GbE parameter editor turns on both RX and TX preamble passthrough.

### 4.1.1.3 Inter-Packet Gap Generation and Insertion

The TX MAC maintains the minimum inter-packet gap (IPG) between transmitted frames required by the IEEE 802.3 Ethernet standard. The deficit idle counter (DIC) maintains the average IPG of 12 bytes.

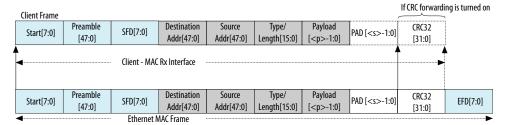

### 4.1.2 50GbE IP Core RX Datapath

The RX MAC receives Ethernet frames and forwards the payload with relevant header bytes to the client after performing some MAC functions on header bytes. The RX MAC processes all incoming valid frames.

### Figure 9. Flow of Client Frame With Preamble Pass-Through Turned On

This figure uses the following notational conventions:

- $\langle p \rangle$  = payload size, which is arbitrarily large.
- $\langle s \rangle$  = number of padding bytes (0-46).

UG-20021 | 2017.11.07

#### Figure 10. Flow of Client Frame With Preamble Pass-Through Turned Off

This figure uses the following notational conventions:

- = payload size, which is arbitrarily large.
- $\langle s \rangle$  = number of padding bytes (0-46).

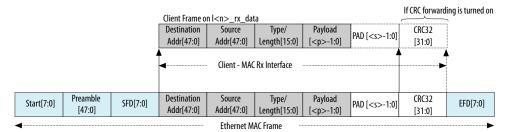

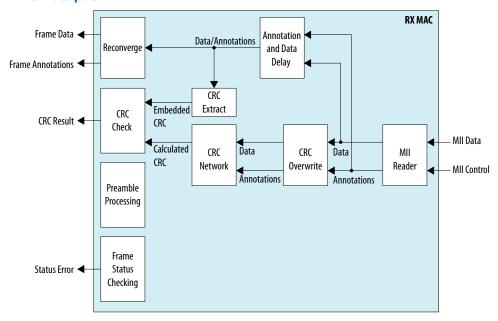

Figure 11. RX MAC Datapath

### 4.1.2.1 IP Core Preamble Processing

If you turn on **Enable preamble passthrough** in the parameter editor, the RX MAC forwards preamble bytes. The TX MAC requires the preamble bytes to be included in the frames at the Avalon-ST interface.

In preamble pass-through mode,  $12\_rx\_preamble[63:0]$  provides the received preamble data to the client. When  $12\_rx\_startofpacket$  is asserted, the  $12\_rx\_preamble[63:0]$  drives the preamble data and  $12\_rx\_data[127:0]$  drives the first 16 bytes of frame data, starting from destination address. The  $12\_rx\_preamble[63:0]$  bus is only present in preamble pass-through mode.

If you turn off **Enable preamble passthrough**, the IP core removes the preamble bytes. 12\_rx\_startofpacket is aligned to the MSB of the destination address.

Note that a single parameter in the 50GbE parameter editor turns on both RX and TX preamble passthrough.

### 4.1.2.2 IP Core Strict SFD Checking

The 50GbE IP core RX MAC checks all incoming packets for a correct Start byte (0xFB). If you turn on **Enable strict SFD check** in the 50GbE parameter editor, you enable the RX MAC to check the incoming preamble and SFD for the following values:

- SFD = 0xD5
- Preamble = 0x5555555555555

The RX MAC checks one or both of these values depending on the values in bits [4:3] of the RXMAC\_CONTROL register at offset 0x50A.

### **Table 9. Strict SFD Checking Configuration**

Enable strict SFD check	0x50A[4]: Preamble Check	0x50A[3]: SFD Check	Fields Checked	Behavior if Check Fails
Off	Don't Care	Don't Care	Start byte	IP core does not recognize a malformed Start byte as a Start byte
On	0	0	Start byte	
	0	1	Start byte and SFD	IP Core drops the
	1	0	Start byte and preamble	packet
	1	1	Start byte and preamble and SFD	

#### **Related Links**

RX MAC Registers on page 44

Describes the RXMAC\_CONTROL register at offset 0x50A.

### 4.1.2.3 IP Core Malformed Packet Handling

While receiving an incoming packet from the Ethernet link, the 50GbE IP core expects to detect a terminate character at the end of the packet. When it detects an expected terminate character, the IP core generates an EOP on the client interface. However, sometimes the IP core detects an unexpected control character when it expects a terminate character.

If the 50GbE IP core detects an Error character, a Start character, an IDLE character, or any other non-terminate control character, when it expects a terminate character, it performs the following actions:

- Generates an EOP.
- Asserts a malformed packet error (12\_rx\_error[0]).
- Asserts an FCS error (12\_rx\_error[1]).

If the IP core subsequently detects a terminate character, it does not generate another EOP indication.

When the IP core receives a packet that contains an error, the IP core identifies it as a malformed packet.

UG-20021 | 2017.11.07

### 4.1.2.4 Length/Type Field Processing

This two-byte header represents either the length of the payload or the type of MAC frame.

- Length/type < 0x600—The field represents the payload length of a basic Ethernet frame. The MAC RX continues to check the frame and payload lengths.
- Length/type >= 0x600—The field represents the frame type. The following frame types are possible:
  - Length/type = 0x8100—VLAN or stacked VLAN tagged frames. The MAC RX continues to check the frame and payload lengths.
  - Length/type = 0x8808—Control frames. The next two bytes are the Opcode field that indicates the type of control frame. For pause frames (Opcode = 0x0001) and PFC frames (Opcode = 0x0101), the MAC RX proceeds with pause frame processing.

Note: The 50G Ethernet IP core passes these frames to the RX client interface and updates the appropriate 12\_rxstatus\_data bits. However, the IP core does not implement flow control.

For other field values, the MAC RX forwards the receive frame to the client.

### 4.1.2.4.1 Length Checking

The MAC function checks the frame and payload lengths of basic, VLAN tagged, and stacked VLAN tagged frames.

The IP core checks that the frame length is valid—is neither undersized nor oversized. A valid frame length is at least 64 (0x40) bytes and does not exceed the following maximum value for the different frame types:

- Basic frames—The number of bytes specified in the MAX\_RX\_SIZE\_CONFIG register.
- VLAN tagged frames—The value specified in the MAX\_RX\_SIZE\_CONFIG register plus four bytes.
- Stacked VLAN tagged frames—The value specified in the MAX\_RX\_SIZE\_CONFIG register plus eight bytes.

If the length/type field in a basic MAC frame or the client length/type field in a VLAN tagged frame has a value less than 0x600, the IP core also checks the payload length. The IP core keeps track of the payload length as it receives a frame, and checks the length against the relevant frame field. The payload length is valid if it satisfies the following conditions:

- The actual payload length matches the value in the length/type or client length/ type field.
- Basic frames—the payload length is between 46 (0x2E)and 1536 (0x0600) bytes, excluding 1536.
- VLAN tagged frames—the payload length is between 42 (0x2A)and 1536 (0x0600), excluding 1536.
- Stacked VLAN tagged frames—the payload length is between 38 (0x26) and 1536 (0x0600), excluding 1536.

The RX MAC does not drop frames with invalid length or invalid payload length. If the frame or payload length is not valid, the MAC function asserts output error bits.

- 12 rx error[2]—Undersized frame.
- 12 rx error[3]—Oversized frame.
- 12\_rx\_error[4]—Payload length error.

If the length field value is greater than the actual payload length, the IP core asserts  $12\_rx\_error[4]$ . If the length field value is less than the actual payload length, the MAC RX considers the frame to have excessive padding and does not assert  $12\_rx\_error[4]$ .

### 4.1.2.5 RX CRC Checking and Dynamic Forwarding

The RX MAC checks the incoming CRC32 for errors. It asserts  $12\_rx\_error[1]$  in the same cycle as  $12\_rx\_endofpacket$  when it detects an error. CRC checking takes several cycles. The packet frame is delayed to align the CRC output with the end of the frame.

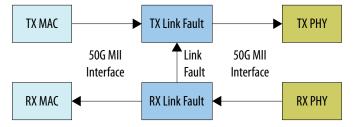

By default, the RX MAC strips off the CRC bytes before forwarding the packet to the MAC client. You can configure the core to retain the RX CRC and forward it to the client by updating the MAC CRC CONFIG register.

### 4.1.3 Link Fault Signaling Interface

Link fault signaling reflects the health of the link. It operates between the remote Ethernet device Reconciliation Sublayer (RS) and the local Ethernet device RS. The link fault modules communicate status during the interframe period.

You enable link fault signaling by turning on **Enable link fault generation** in the parameter editor. For bidirectional fault signaling, the IP core implements the functionality defined in the *IEEE 802.3ba 40G/100G Ethernet Standard* and *Ethernet Clause 81.3.4* based on the LINK\_FAULT configuration register settings. For unidirectional fault signaling, the core implements *Clause 66 of the IEEE 802.3-2012 Ethernet Standard*.

Figure 12. Link Fault Block Diagram

### Local Fault (LF)

If an Ethernet PHY sublayer detects a fault that makes the link unreliable, it notifies the RS of the local fault condition. If unidirectional is not enabled, the core follows *Clause 46*. The RS stops sending MAC data, and continuously generates a remote fault status on the TX datapath. After a local fault is detected, the RX PCS modifies the MII data and control to send local fault sequence ordered sets. Refer to *Link Fault Signaling Based On Configuration and Status* below.

UG-20021 | 2017.11.07

The RX PCS cannot recognize the link fault under the following conditions:

- The RX PCS is not fully aligned.
- The bit error rate (BER) is high.

### Remote Fault (RF)

If unidirectional is not enabled, the core follows *Clause 46*. If the RS receives a remote fault status, the TX datapath stops sending MAC data and continuously generates idle control characters. If the RS stops receiving fault status messages, it returns to normal operation, sending MAC client data. Refer to *Link Fault Signaling Based On Configuration and Status* below.

### **Link Status Signals**

The MAC RX generates two link fault signals: local\_fault\_status and remote fault status.

Note:

These signals are real time status signals that reflect the status of the link regardless of the settings in the link fault configuration register.

This register is generated only if you turn on **Enable link fault generation**. The MAC TX interface uses the link fault status signals for additional link fault signaling.

### Table 10. Link Fault Signaling Based On Configuration and Status

For more information about the  ${\tt LINK\_FAULT}$  register, refer to TX MAC Registers.

LINK	_FAULT Re	gister (0x	405)	Real Time I	Link Status	Configu Beha		Comment

### 4.1.4 50 GbE RX PCS

The soft RX PCS interfaces to the hard PCS and PMA blocks configured in 66:64 10G PCS Basic Generic Mode, with bitslip enabled. The hard PCS drives two, 66-bit output streams containing four virtual lanes to the soft RX PCS. The soft RX PCS implements word lock, lane reordering, descrambling, and MII decoding.

Figure 13. High Level Block Diagram of the Soft TX PCS

### **4.2 User Interface to Ethernet Transmission**

The IP core reverses the bit stream for transmission per Ethernet requirements. The transmitter handles the insertion of the inter-packet gap, frame delimiters, and padding with zeros as necessary. The transmitter also handles FCS computation and insertion.

UG-20021 | 2017.11.07

The IP core transmits complete packets. After transmission begins, it must complete with no IDLE insertions. Between the end of one packet and the beginning of the next packet, the data input is not considered and the transmitter sends IDLE characters. An unbounded number of IDLE characters can be sent between packets.

### 4.2.1 Order of Transmission

The IP core transmits bytes on the Ethernet link starting with the preamble and ending with the FCS in accordance with the IEEE 802.3 standard. On the transmit client interface, the IP core expects the client to send the most significant bytes of the frame first, and to send each byte in big-endian format. Similarly, on the receive client interface, the IP core sends the client the most significant bytes of the frame first, and orders each byte in big-endian format.

### Figure 14. Byte Order on the Client Interface Lanes

Describes the byte order on the Avalon-ST interface. Destination Address[40] is the broadcast/multicast bit (a type bit), and Destination Address[41] is a locally administered address bit.

	0	) estina	ntion Ad	ddress (	DA)			Sourc	e Addı	ress (S	A)		Typ Lengt			Data (D)	
0ctet	5	4	3	2	1	0	5	4	3	2	1	0	1	0	00		NN
Bit	[47:40]	[39:32]	[31:24]	[23:16]	[15:8]	[7:0]	[47:40]	[39:32]	[31:24]	[33:16]	[15:8]	[7:0]	[15:8]	[7:0]	MSB[7:0]		[SB[7:0]

For example, the destination MAC address includes the following six octets AC-DE-48-00-00-80. The first octet transmitted (octet 0 of the MAC address described in the 802.3 standard) is AC and the last octet transmitted (octet 5 of the MAC address) is 80. The first bit transmitted is the low-order bit of AC, a zero. The last bit transmitted is the high order bit of 80, a one.

The preceding table and the following figure show that in this example, 0xAC is driven on DA5 (DA[47:40]) and 0x80 is driven on DA0 (DA[7:0]).

Figure 15. Octet Transmission on the 50GbE Avalon-ST Interface

In the following diagram Preamble pass through is disabled. clk\_txmac DA5 D2 D18 DA5 D2 D82 DA5 D2 l2\_tx\_data[127:120] DA4 D3 D19 DA4 D3 D83 DA4 D3 12\_tx\_data[119:112] D20 D84 l2\_tx\_data[111:104] DA3 D4 DA3 D4 DA3 D4 DA2 D5 D21 DA2 D5 D85 DA2 D5 l2\_tx\_data[103:96] D6 D86 DA1 D22 DA1 D6 DA1 D6 12\_tx\_data[95:88] DA0 D7 D23 DA0 D7 D87 DA0 D7 12\_tx\_data[87:80] SA5 D8 D24 SA5 D8 D88 SA5 D8 12\_tx\_data[79:72] SA4 D9 D25 SA4 D9 D89 SA4 D9 12\_tx\_data[71:64] SA3 D10 D26 SA3 D10 D90 SA3 D10 12\_tx\_data[63:56] SA2 D11 12\_tx\_data[55:48] SA2 D11 SA2 D11 D91 SA1 D12 SA1 D12 D92 SA1 D12 l2\_tx\_data[47:40] D13 D13 D93 SA0 D13 SA0 SA0 12\_tx\_data[39:32] TL1 D14 TL1 D14 D94 TL1 D14 12\_tx\_data[31:24] TL0 D15 TL0 D15 D95 TL0 D15 12\_tx\_data[23:16] D0 D16 D0 D16 D0 D16 12\_tx\_data[15:8] D1 D17 D1 D17 D1 D17 12\_tx\_data[7:0] 12\_tx\_startofpacket I2\_tx\_endofpacket

### 4.2.2 Bit Order For TX and RX Datapaths

I2\_tx\_empty[3:0]

The TX bit order matches the placement shown in the PCS lanes as illustrated in *IEEE Standard for Ethernet, Section 4, Figure 49-5*. The RX bit order matches the placement shown in *IEEE Standard for Ethernet, Section 4, Figure 49-6*.

### **Related Links**

### **IEEE** website

The IEEE Standard for Ethernet, Section 4 is available on the IEEE website.

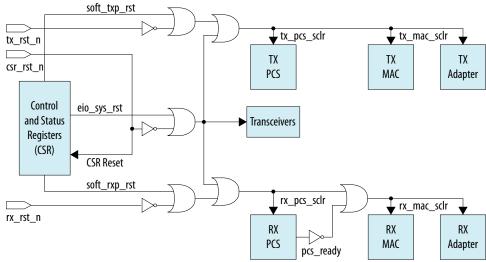

### **5** Reset

Control and Status registers control three parallel soft resets. These soft resets are not self-clearing. Software clears them by writing to the appropriate register. Asserting the external hard reset csr\_rst\_n returns Control and Status registers to their original values.

### Figure 16. Conceptual Overview of Reset Logic

The three hard resets are top-level ports. The soft resets are internal signals which are outputs of the PHY\_CONFIG register. Software writes the appropriate bit of the PHY\_CONFIG to assert a soft reset.

The internal soft reset signals reset the following functions:

- soft\_txp\_rst: Resets the IP core in TX direction. Resets the TX PCS, MAC, and adapter. This soft reset leads to deassertion of tx\_lanes\_stable output signal.
- soft\_rxp\_rst: Resets the IP core in RX direction. Resets the RX PCS, MAC, and adapter. This soft reset leads to the deassertion of rx\_pcs\_ready output signal.
- eio\_sys\_rst: Resets the IP core. Resets the TX and RX MACs, PCS, adapters, and transceivers. Does not reset the Control and Status registers. This soft reset leads to the deassertion of tx\_lanes\_stable and rx\_pcs\_ready output signal.

### **Table 11.** Avalon-ST TX Datapath

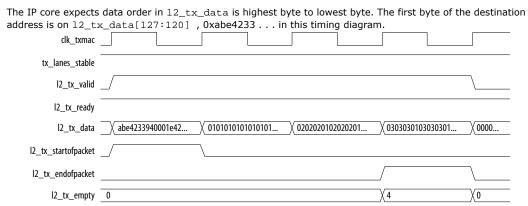

All interface signals are clocked by the  ${\tt clk\_txmac}$  clock.

Output	Clock for the TX logic. Derived from pll_refclk, and is an output from
	the 50GbE IP core. clk_txmac is guaranteed to be stable when tx_lanes_stable is asserted. The frequency of this clock is 390.625 MHz.All TX MAC interface signals are synchronous to clk_txmac.
Input	Data Input to MAC. Bit 127 is the MSB and bit 0 is the LSB. Bytes are read in the usual left to right order.  The 50GbE IP core does not process incoming frames of less than nine bytes correctly. You must ensure such frames do not reach the TX client interface.  You must send each TX data packet without intermediate idle cycles. Therefore, you must ensure your application can provide the data for a single packet in consecutive clock cycles. If data might not be available otherwise, you must buffer the data in your design and wait to assert 12_tx_startofpacket when you are assured the packet data to send on 12_tx_data[127:0] is available or will be available on time.
Input	User preamble data. Available when you select PREAMBLE PASS-THROUGH mode. User logic drives the custom preamble data when 12_tx_startofpacket is asserted.
Input	When asserted, indicates valid data is available on 12_tx_data[127:0]. You must assert this signal continuously between the assertions of 12_tx_startofpacket and 12_tx_endofpacket for the same packet.
Input	When asserted, indicates the first byte of a frame. When 12_tx_startofpacket is asserted, the MSB of 12_tx_data drives the first byte of the packet.
Input	When asserted, indicates the end of a packet. The IP core ignores packets with length less than nine bytes.
	Specifies the number of empty bytes on 12_tx_data when 12_tx_endofpacket is asserted.
Output	When asserted, indicates that the MAC can accept the data.
Output	When asserted, indicates that 12_txstatus_error[6:0] is driving valid data.
Output	Specifies information about the transmit frame. The following fields are defined:  • [Bit 39]: When asserted, indicates a PFC frame  • [Bit 38]: When asserted, indicates a unicast frame  • Bit[37]: When asserted, indicates a multicast frame  • Bit[36]: When asserted, indicates a broadcast frame  • Bit[35]: When asserted, indicates a pause frame  • Bit[34]: When asserted, indicates a control frame  • Bit[33]: When asserted, indicates a VLAN frame
	Input Input Input Output Output

Signal	Direction	Description
		Bit[32]: When asserted, indicates a stacked VLAN frame Bits[31:16]: Specifies the frame length from the first byte of the destination address to the last bye of the FCS Bits[15:0]: Specifies the payload length
12_txstatus_error[6:0]	Output	Specifies the error type in the transmit frame. The following fields are defined:  • Bits[6:3]: Reserved  • Bit[2]: Payload length error  • Bit[1]: Oversized frame  • Bit[0]: Reserved

### Figure 18. Client to 50GbE MAC Avalon-ST Interface

### **Avalon Interface Specifications**

Detailed information about Avalon-ST interfaces.

# **6.2 RX MAC Interface to User Logic**

The RX MAC provides an Avalon-ST interface to the FPGA fabric. The datapath comprises 2, 64-bit words.

### Table 12. Avalon-ST RX Datapath

All interface signals are clocked by the clk\_rxmac clock.

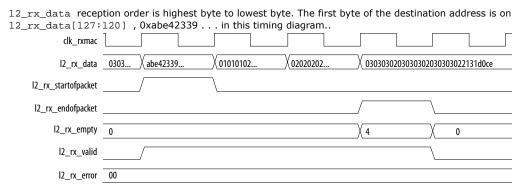

Signal	Direction	Description
clk_rxmac	Output	Clock for the RX MAC. Recovered from the incoming data. This clock is guaranteed stable when $rx\_pcs\_ready$ is asserted. The frequency of this clock is 390.625 MHz. All RX MAC interface signals are synchronous to $clk\_rxmac$ .
12_rx_data[127:0]	Output	Data output from the MAC. Bit 127 is the MSB and bit 0 is the LSB. Bytes are read in the usual left to right order. The IP core reverses the byte order to meet the requirements of the Ethernet standard.
l2_rx_preamble[63:0]	Output	Received preamble data. Available when you select PREAMBLE PASS-THROUGH mode.  Valid when 12_rx_startofpacket is asserted.
		continued

Signal	Direction	Description
12_rx_valid	Output	When asserted, indicates that 12_rx_data[127:0] is driving data. The IP core need not assert this signal continuously between the assertions of 12_tx_startofpacket and 12_tx_endofpacket for the same packet. During alignment marker cycles, the IP core drives IDLE cycles.
12_rx_startofpacket	Output	When asserted, indicates the first byte of a frame.  In PREAMBLE PASS-THROUGH mode, marks the first byte of the preamble.
12_rx_endofpacket	Output	When asserted, indicates the last data byte of a frame, before the frame check sequence (FCS). In CRC pass-through mode, it is the last byte of the FCS. The packet can end at any byte position.
12_rx_empty[3:0]	Output	Specifies the number of empty bytes when 12_rx_endofpacket is asserted.  The packet can end at any byte position. The empty bytes are the low-order bytes.
12_rx_error[5:0]	Output	When asserted in the same cycle as 12_rx_endofpacket, indicates the current packet should be treated as an error packet. The 6 bits of 12_rx_error specify the following errors:  12_rx_error[5]: Unused.  12_rx_error[4]: Payload length error. If the length field is <1535 bytes, the received payload length is less than what is advertised in payload length field.  12_rx_error[3]: Oversized frame. The frame size is greater than the value specified in the RXMAC_SIZE_CONFIG register.  12_rx_error[2]: Undersized frame - The frame size is less than 64 bytes. Frame size = header size + payload size.  12_rx_error[1]: CRC Error. The computed CRC value differs from the received CRC.  12_rx_error[0]: Malformed packet. The packet is terminated with a non-terminate control character. When this bit is asserted, 12_rx_error[1] is also asserted.
12_rxstatus_valid	Output	When asserted, indicates that 12_rxstatus_data is driving valid data.
12_rxstatus_data[39:0]	Output	Specifies information about the received frame. The following fields are defined:  • [Bit 39]: When asserted, indicates a PFC frame  • [Bit 38]: When asserted, indicates a unicast frame  • Bit[37]: When asserted, indicates a multicast frame  • Bit[36]: When asserted, indicates a broadcast frame  • Bit[35]: When asserted, indicates a pause frame  • Bit[34]: When asserted, indicates a control frame  • Bit[33]: When asserted, indicates a VLAN frame  • Bit[32]: When asserted, indicates a stacked VLAN frame  • Bits[31:16]: Specifies the frame length from the first byte of the destination address to the last bye of the FCS  • Bits[15:0]: Specifies the payload length

#### Figure 19. 50GbE MAC to Client Avalon-ST Interface

### **Avalon Interface Specifications**

Detailed information about Avalon-ST interfaces.

### **6.3 Transceivers**

The transceivers require a separately instantiated advanced transmit (ATX) PLL to generate the high speed serial clock. For the 50GbE IP core, you can use the same ATX PLL for both transceivers. In comparison to the fractional PLL (fPLL) and clock multiplier unit PLL, the ATX PLL has the best jitter performance and supports the highest frequency operation.

### **Table 13.** Transceiver Signals

Signal	Direction	Description
tx_serial[1:0]	Output	TX transceiver signal. Each ${\tt tx\_serial}$ bit becomes two physical pins that form a differential pair.
rx_serial[1:0]	Input	RX transceiver signals. Each $rx\_serial$ bit becomes two physical pins that form a differential pair.
clk_ref	Input	The PLL reference clock. Input to the clock data recovery (CDR) circuitry in the RX PMA. The frequency of this clock is 644.53125 MHz.
tx_serial_clk[1:0]	Input	High speed serial clock driven by the ATX PLL. The frequency of this clock is 12.890625 GHz.
tx_pll_locked	Input	Lock signal from ATX PLL. Indicates all ATX PLL(s) are locked.

# **6.4 Transceiver Reconfiguration Signals**

You access the transceiver control and status registers using the transceiver reconfiguration interface. This is an Avalon-MM interface.

UG-20021 | 2017.11.07

The Avalon-MM interface implements a standard memory-mapped protocol. You can connect an Avalon master to this bus to access the registers of the embedded Transceiver PHY IP core.

# Table 14. Reconfiguration Interface Ports with Shared Native PHY Reconfiguration Interface

All interface signals are clocked by the reconfig\_clk clock.

Port Name	Direction	Description	
reconfig_clk	Input	Avalon clock. The clock frequency is 100-125 MHz. All signals transceiver reconfiguration interface signals are synchronous to reconfig_clk.	
reconfig_reset	Input	Resets the Avalon-MM interface and all of the registers to which it provides access.	
reconfig_write	Input	Write enable signal. Signal is active high.	
reconfig_read	Input	Read enable signal. Signal is active high.	
reconfig_address[10:0]	Input	Address bus.	
reconfig_writedata[31:0]	Input	A 32-bit data write bus. reconfig_address specifies the address.	
reconfig_readdata[31:0]	Output	A 32-bit data read bus. Drives read data from the specified address. Signal is valid after reconfig_waitrequest is deasserted.	
reconfig_waitrequest	Output	Indicates the Avalon-MM interface is busy. Keep the reconfig_write or reconfig_read asserted until reconfig_waitrequest is deasserted.	

### **Related Links**

[Transceiver Reconfiguration] Ports and Parameters section of the *Arria 10 Transceiver PHY User Guide* 

Provides more information about the transceiver reconfiguration interface, including timing diagrams for reads and writes.

### **6.5 Avalon-MM Management Interface**

You access control and status registers using an Avalon-MM management interface. The interface responds regardless of the link status. It also responds when the IP core is in a reset state driven by any reset signal or soft reset other than the <code>csr\_rst\_n</code> signal. Asserting the <code>csr\_rst\_n</code> signal resets all control and status registers except the statistics counters; while this reset is in process, the Avalon-MM management interface does not respond.

**Table 15.** Avalon-MM Management Interface

Signal	Direction	Description
clk_status	Input	The clock that drives the control and status registers. The frequency of this clock is 100 MHz.
reset_status	Input	Connect this signal to 1'b0. This signal remains visible as a top-level signal for backward compatibility.
status_addr[15:0]	Input	Drives the Avalon-MM register address.
status_read	Input	When asserted, specifies a read request.
status_write	Input	When asserted, specifies a write request.
status_readdata[31:0]	Output	Drives read data. Valid when status_readdata_valid is asserted.
status_readdata_valid	Output	When asserted, indicates that status_read_data[31:0] is valid.
status_writedata[31:0]	Input	Drives the write data. The packet can end at any byte position. The empty bytes are the low-order bytes.
status_waitrequest	Output	Indicates that the control and status interface is not ready to complete the transaction. status_waitrequest is only used for read transactions.

#### **Related Links**

## 6.6 Miscellaneous Status and Debug Signals

The miscellaneous status and debug signals are asynchronous.

**Table 16.** Miscellaneous Status and Debug Signals

Signal	Direction	Description	
tx_lanes_stable	Output	Asserted when all TX lanes are stable and ready to transmit data.	
rx_block_lock	Output	Asserted when all lanes have identified 66-bit block boundaries in the serial data stream.	
rx_am_lock	Output	Asserted when all lanes have identified alignment markers in the data stream.	
rx_pcs_ready	Output	Asserted when the RX lanes are fully aligned and ready to receive data.	
		continued	

Signal	Direction	Description
local_fault_status	Output	Asserted when the RX MAC detects a local fault. This signal is available if you turn on <b>Enable link fault generation</b> in the parameter editor.
remote_fault_status	Output	Asserted when the RX MAC detects a remote fault. This signal is available if you turn on <b>Enable link fault generation</b> in the parameter editor.
unidirectional_en	Output	Asserted if the IP core includes <i>Clause 66</i> for unidirectional support. This signal is available if you turn on <b>Enable link fault generation</b> in the parameter editor.
link_fault_gen_en	Output	Asserted if the IP core includes <i>Clause 66</i> for unidirectional support. This signal is available if you turn on <b>Enable link fault generation</b> in the parameter editor.

#### **Related Links**

Debugging the Link on page 46

## **6.7 Reset Signals**

The IP core has three external hard reset inputs. These resets are asynchronous and are internally synchronized. Assert resets for ten cycles or until you observe the effect of their specific reset. Asserting the external hard reset csr\_rst\_n returns control and status registers to their original values. rx\_pcs\_ready and tx\_lanes\_stable are asserted when the core has exited reset successfully.

**Table 17.** Reset Signals

Signal	Direction	Description
tx_rst_n	Input	Active low hard reset signal. Resets the TX interface, including the TX PCS and TX MAC. This reset leads to the deassertion of the tx_lanes_stable output signal.
rx_rst_n	Input	Active low hard reset signal. Resets the RX interface, including the RX PCS and RX MAC. This reset leads to the deassertion of the rx_pcs_ready output signal.
csr_rst_n	Input	Active low hard global reset. Resets the full IP core. Resets the TX MAC, RX MAC, TX PCS, RX PCS, adapters, transceivers, and control and status registers. This reset leads to the deassertion of the tx_lanes_stable and rx_pcs_ready output signals.

## 7 Control and Status Register Descriptions

This section provides information about the memory-mapped registers. You access these registers using the IP core Avalon-MM control and status interface. The registers use 32-bit addresses; they are not byte addressable.

Write operations to a read-only register field have no effect. Read operations that address a Reserved register return an unspecified result. Write operations to Reserved registers have no effect. Accesses to registers that do not exist in your IP core variation, or to register bits that are not defined in your IP core variation, have an unspecified result. You should consider these registers and register bits Reserved. Although you can only access registers in 32-bit read and write operations, you should not attempt to write or ascribe meaning to values in undefined register bits.

### **Table 18.** Register Base Addresses

Word Offset	Register Type
0x300-0x3FF	PHY registers
0x400-0x4FF	TX MAC registers
0x500-0x5FF	RX MAC registers

#### Note:

Do not attempt to access any register address that is Reserved or undefined. Accesses to registers that do not exist in your IP core variation have unspecified results.

ISO 9001:2008 Registered

Addr	Name	Description	Reset	Access
0x303	PHY_NAME_1	Next characters of IP core variation identifier string, "GE".	0x0000 4745	RO
0x304	PHY_NAME_2	Final characters of IP core variation identifier string, "pcs".	0x0070 6373	RO
0x310	PHY_CONFIG	PHY configuration registers. The following bit fields are defined:  • Bit[0]::eio_sys_rst. Full system reset (except registers). Set this bit to initiate	26'hX_2'b0_1'bX_3'b 0 (X= don't care)	RW
		<ul><li>the internal reset sequence.</li><li>Bit[1]: soft_txp_rst. TX soft reset. Resets TX PCS, MAC, and adapter.</li></ul>		
		<ul> <li>Bit[2]: soft_rxp_rst. RX soft reset. Resets RX PCS, MAC, and adapter.</li> <li>Bit[3]: Reserved.</li> <li>Bit[4]: set_ref_lock. Directs the RX</li> </ul>		
		CDR PLL to lock to the reference clock.  Bit[5]: set_data_lock. Directs the RX CDR PLL to lock to data.  Bits[31:6]: Reserved.		
0x312	WORD_LOCK	When asserted, indicates that the virtual channel has identified 66 bit block boundaries in the serial data stream.	30'hX4'b0	RO
0x313	EIO_SLOOP	Serial PMA loopback. Setting a bit puts the corresponding transceiver in serial loopback mode. In serial loopback mode, the TX lane loops back to the RX lane on an internal loopback path.	30'hX2'b00	RW
0x314	EIO_FLAG_SEL	Supports indirect addressing of individual FIFO flags in the PCS Native PHY IP core. Program this register with the encoding for a specific FIFO flag. The flag values (one per transceiver) are then accessible in the EIO_FLAGS register.  The value in the EIO_FLAG_SEL register directs the IP core to make available the following FIFO flag:  3'b000: TX FIFO full  3'b001: TX FIFO empty  3b010: TX FIFO partially full  3'b011: TX FIFO partially empty  3b100: RX FIFO full  3b101: RX FIFO empty	29'hX3'b0	RW
		<ul><li> 3b110: RX FIFO partially full</li><li> 3b111: RX FIFO partially empty</li></ul>		
0x315	EIO_FLAGS	PCS indirect data. To read a FIFO flag, set the value in the EIO_FLAG_SEL register to indicate the flag you want to read. After you specify the flag in the EIO_FLAG_SEL register, each bit [n] in the EIO_FLAGS register has the value of that FIFO flag for the transceiver channel for lane [n].	30'hX2'b0	RO
0x321	EIO_FREQ_LOCK	Each asserted bit indicates that the corresponding lane RX clock data recovery (CDR) phase-locked loop (PLL) is locked.	30'hX2'b00	RO

Addr	Name	Description	Reset	Access
		Bit[0]: Indicates if the TX PCS is ready Bit [1]: Indicates if the TX MAC PLL is locked. Bit[2]: Indicates if the RX CDR PLL is locked		
0x323	FRM_ERR	Each asserted bit indicates that the corresponding virtual lane has a frame error. You can read this register to determine if the IP core sustains a low number of frame errors, below the threshold to lose word lock. These bits are sticky, unless the IP core loses word lock. Write 1'b1 to the SCLR_FRM_ERR register to clear.  If the IP core loses word lock, it clears this register.	28'hX_4'b0	RO
0x324	SCLR_FRM_ERR	Synchronous clear for FRM_ERR register. Write 1'b1 to this register to clear the FRM_ERR register and bit [1] of the LANE_DESKEWED register. A single bit clears all sticky framing errors. This bit does not auto-clear. Write a 1'b0 to continue logging frame errors.	0x0	RW
0x325	EIO_RX_SOFT_PURGE_S	Set bit [0] to clear the RX FIFO for both physical lanes.	31'bX_1'b0	RW
0x326	RX_PCS_FULLY_ALIGNED _S	Indicates the RX PCS is fully aligned and ready to accept traffic.  • Bit[0]: RX PCS fully aligned status.	31'hX1'b0	RO
0x328	AM_LOCK	When asserted indicates that the physical channel has identified virtual lane alignment markers in the data stream.	28'hX_4'b0	RO
0x329	LANE_DESKEWED	The following encodings are defined:  Bit [0]: Indicates all lanes are deskewed.  Bit [1]: When asserted indicates a change in lanes deskewed status. To clear this sticky bit, write 1'b1 to the corresponding bit of the SCLR_FRM_ERR register. This is a latched signal.	30'hX2'b00	RO
0x330	PCS_VLANE	<ul> <li>The following encodings are defined:</li> <li>Bit [1:0]: First virtual index for physical lane 0.</li> <li>Bit [3:2]: Second virtual index for physical lane 0.</li> <li>Bit [5:4]: First virtual index for physical lane 1.</li> <li>Bit [7:6]: Second virtual index for physical lane 1.</li> </ul>	24'bX8'b0	RO
0x340	KHZ_REF	Reference clock frequency in KHz, assuming the clk_status clock is 100 MHz. The reference clock frequency is the value in KHZ times the frequency of the clk_status clock, divided by 100.	0x0000 0000	RO
0x341	KHZ_RX	RX clock (clk_rxmac) frequency in KHz, assuming the clk_status clock has the frequency of 100 MHz. The RX clock	0x0000 0000	RO
			cor	tinued

UG-20021 | 2017.11.07

Addr	Name	Description	Reset	Access
		frequency is the value in KHZ times the frequency of the clk_status clock, divided by 100.		
0x342	KHZ_TX	TX clock (clk_txmac) frequency in KHz, assuming the clk_status clock has the frequency of 100 MHz. The TX clock frequency is the value in KHZ times the frequency of the clk_status clock, divided by 100.	0x0000 0000	RO

## **7.2 TX MAC Registers**

## **Table 20. TX MAC Registers**

Addr	Name	Description	Reset	Access
0x400	TXMAC_REVID	TX MAC revision ID for 50G TX MAC CSRs.	0x0916 2016	RO
0x401	TXMAC_SCRATCH	Scratch register available for testing.	0x0000 0000	RW
0x402	TXMAC_NAME_0	First 4 characters of IP core variation identifier string, "50gMACTxCSR".	0x3530 674D	RO
0x403	TXMAC_NAME_1	Next 4 characters of IP core variation identifier string, "ACTx".	0x4143 5478	RO
0x404	TXMAC_NAME_2	Final 4 characters of IP core variation identifier string, "00CSR". The "00" is unprintable.	0x0043 5352	RO
0x405	LINK_FAULT	Link Fault Configuration Register. The following bits are defined:  • Force Remote Fault bit[3]: When link fault generation is enabled, stops data transmission and forces transmission of a remote fault.  • Disable Remote Fault bit[2]: When both link fault reporting and unidirectional transport are enabled, the core transmits data and does not transmit remote faults (RF). This bit takes effect when the value of this register is 28'hX4'b0111.  • Unidir Enable bit[1]: When asserted, the core includes Clause 66 support for the remote link fault reporting on the Ethernet link.  • Link Fault Reporting Enable bit[0]: The following encodings are defined:  — 1'b1: The PCS generates the proper fault sequence on Ethernet link, when conditions are met.  — 1'b0: The PCS does not generate the fault sequence.	28'hX_4'b0001	RW
0x406	IPG_COL_REM	Specifies the number of IDLE columns to be removed in every Alignment Marker period to compensate for alignment marker insertion. You can program this register to a larger value than the default value, for clock compensation.	0xXXXX 0004	RW

Addr	Name	Description	Reset	Access
		Bits [31:8] of this register are Reserved.		
0x407	MAX_TX_SIZE_CONFIG	Specifies the maximum TX frame length. Frames that are longer are considered oversized. They are transmitted, but also increment the CNTR_TX_OVERSIZE register. Bits [31:16] of this register are Reserved.	0xXXXX 2580	RW
0x40A	TXMAC_CONTROL	TX MAC Control Register. A single bit is defined:  Bit [1] – VLAN detection disabled. This bit is deasserted by default, implying VLAN detection is enabled.	30'hX2'b0X	RW

## **7.3 RX MAC Registers**

### **Table 21. RX MAC Registers**

Addr	Name	Description	Reset	Access
0x500	RXMAC_REVID	RX MAC revision ID for 50G Ethernet IP core.	0x0916 2016	RO
0x501	RXMAC_SCRATCH	Scratch register available for testing.	0x0000 0000	RW
0x502	RXMAC_NAME_0	First 4 characters of IP core variation identifier string, "50gMACRxCSR".	0x3530 674D	RO
0x503	RXMAC_NAME_1	Next 4 characters of IP core variation identifier string, "ACRx".	0x4143 5278	RO
0x504	RXMAC_NAME_2	Final 4 characters of IP core variation identifier string, "00CSR". The "00" is unprintable.	0x0043 5352	RO
0x506	RXMAC_SIZE_CONFIG	Specifies the maximum frame length available. The MAC asserts 12_rx_error[3] when the length of the received frame exceeds the value of this register.	0xXXXX 2580	RW
0x507	MAC_CRC_CONFIG	The RX CRC forwarding configuration register. The following encodings are defined:  • 1'b0: Remove RX CRC, do not forward it to the RX client interface  • 1'b1: Retain RX CRC, forward it to the RX client interface  In either case, the IP core checks the incoming RX CRC and flags errors.	31'hX1'b0	RW
0x508	LINK_FAULT	Link Fault Status Register. For regular (non-unidirectional) Link Fault, implements <i>IEEE 802.3 BA Ethernet Clause 81.3.4.</i> For unidirectional Link Fault, implements <i>IEEE 802.3 Ethernet Clause 66.</i>	30'hX2'b00	RO
0x50A	RXMAC_CONTROL	RX MAC Control Register. The following bits are defined:	27'h0_5'b11X0X	RW

IP Core Strict SFD Checking on page 24

## 8 Debugging the Link

Begin debugging your link at the most basic level, with word lock. Then, consider higher level issues.

The following steps should help you identify and resolve common problems that occur when bringing up a 50GbE IP core link:

- Establish word lock—The RX lanes should be able to achieve word lock even in the
  presence of extreme bit error rates. If the IP core is unable to achieve word lock,
  check the transceiver clocking and data rate configuration. Check for cabling
  errors such as the reversal of the TX and RX lanes. Check the clock frequency
  monitors in the Control and Status registers.
  - To check for word lock: Clear the FRM\_ERR register by writing the value of 1 followed by another write of 0 to the SCLR\_FRM\_ERR register at offset 0x324. Then read the FRM\_ERR register at offset 0x323. If the value is zero, the core has word lock. If non-zero the status is indeterminate
- When having problems with word lock, check the EIO\_FREQ\_LOCK register at address 0x321. The values in this register define the status of the recovered clock. In normal operation, all the bits should be asserted. A non-asserted (value-0) or toggling logic value on the bit that corresponds to any lane, indicates a clock recovery problem. Clock recovery difficulties are typically caused by the following problems:
  - Bit errors
  - Failure to establish the link
  - Incorrect clock inputs to the IP core
- 3. Check the PMA FIFO levels by selecting appropriate bits in the EIO\_FLAG\_SEL register and reading the values in the EIO\_FLAGS register. During normal operation, the TX and RX FIFOs should be nominally filled. Observing a the TX FIFO is either empty or full typically indicates a problem with clock frequencies. The RX FIFO should never be full, although an empty RX FIFO can be tolerated.
- 4. Establish lane deskew status by reading bit[0] of the LANE\_DESKEWED register at address 0x329. Bit[1] of the LANE\_DESKEWED register indicates if the deskew lock has ever toggled since reset or SCLR\_FRM\_ERR cleared an error. 50GbE currently supports up to 16 words of skew among the virtual lanes. The inability to deskew implies a higher than supported skew between the virtual lanes.
- 5. Establish the alignment marker lock—Virtual lane alignment marker lock requires a moderate quality transceiver connection. If the lock is completely absent, recheck the alignment marker period. If the lock is intermittent, recheck the transceiver physical connection and analog settings.
  - To check for alignment marker lock: Check the value of the  $rx_pcs_ready$  signal or read bit [0] of the  $RX_PCS_FULLY_ALIGNED_S$  register at offset 0x326. The value of 1 on the signal or in the register bit indicates the RX PCS is fully aligned.

Intel Corporation. All rights reserved. Intel, the Intel logo, Altera, Arria, Cyclone, Enpirion, MAX, Nios, Quartus and Stratix words and logos are trademarks of Intel Corporation or its subsidiaries in the U.S. and/or other countries. Intel warrants performance of its FPGA and semiconductor products to current specifications in accordance with Intel's standard warranty, but reserves the right to make changes to any products and services at any time without notice. Intel assumes no responsibility or liability arising out of the application or use of any information, product, or service described herein except as expressly agreed to in writing by Intel. Intel customers are advised to obtain the latest version of device specifications before relying on any published information and before placing orders for products or services.

- 6. Establish lane integrity—When operating properly, the lanes should not experience bit errors at a rate greater than roughly one per hour per day. Bit errors within data packets are identified as FCS errors. Bit errors in control information, including IDLE frames, generally cause errors in XL/CGMII decoding. The bit interleaved parity (BIP) mechanism is a diagonal parity computation that enables tracing a protocol error back to a physical lane.
- 7. Verify packet traffic—The Ethernet protocol includes automatic lane reordering so the higher levels should follow the PCS. If the PCS is locked, but higher level traffic is corrupted, there may be a problem with the remote transmitter virtual lane tags.
- 8. Tuning—You can adjust transceiver analog parameters to improve the bit error rate.

In addition, your IP core can experience loss of signal on the Ethernet link after it is established. In this case, the TX functionality is unaffected, but the RX functionality is disrupted. The following symptoms indicate a loss of signal on the Ethernet link:

- The IP core deasserts the rx\_pcs\_ready signal, indicating the IP core has lost alignment marker lock.
- The IP core deasserts the RX PCS fully aligned status bit (bit [0]) of the RX\_PCS\_FULLY\_ALIGNED\_S register at offset 0x326. This change is linked to the change in value of the rx\_pcs\_ready signal.
- If **Enable link fault generation** is turned on, the IP core sets local fault status to the value of 1.
- The IP core asserts the Local Fault Status bit (bit [0]) of the Link\_Fault register at offset 0x308. This change is linked to the change in value of the local\_fault\_status signal.
- The IP core triggers the RX digital reset process by asserting soft\_rxp\_rst.

## **9 Document Revision History**

Date	Quartus Prime Version	Changes
		Added link to KDB Answer that provides workaround for potential jitter on Arria 10 devices due to cascading ATX PLLs in the IP core. Refer to Handling Potential Jitter in Arria 10 Devices on page 17 and to Compiling the Full Design and Programming the FPGA on page 17.
		Reorganized Features list for reading clarity. Refer to 50GbE IP Core Supported Features on page 6.
2017.11.09	17.0	Clarified that both read and write accesses to undefined registers or register fields, including accesses to registers and register fields not defined in the current IP core variation, return unspecified results. Refer to Control and Status Register Descriptions on page 40.
		Clarified that the reset_status signal remains visible in future releases for backward compatiblity, rather than being removed. The design must tie this input signal low. Refer to Avalon-MM Management Interface on page 38.
2017.05.08	17.0	Initial public release.
